1 Lecture 2 - Training Deep Neural Networks

Someone asked the question when should you use DL and or something simpler like Binary Trees. The answer was that there are two dimensions

1. Is explaining the model more important? Go with simpler models
2. Is accuracy more important? Then go with that and dont worry how complex the model is.

By default just choose **RELU** as your non linear function.

Lets design the layout of the network

1. Choose number of hidden layers and number of neurons in each layer - We choose 1 Hidden layer with 16 RELU neurons
2. Pick the right output layer - Sigmoid

If there are no hidden layers its just **Linear Regression**.

Too many layers can result in overfitting.

If you want to emit a probability in the end then use Sigmoid function. Thats why the output layer is sigmoid. HE was explaining a medical diagnosis problem.
